Answer: BCE. To establish an electric

circuit, charge must be moved from low energy to high energy. Once at high energy, the charge spontaneously flows through the conducting wires and other conducting elements of the circuit back down to the low energy terminal. A battery's role is to supply the energy which is required to move the charge from the -

terminal to the + terminal of the battery.

Answer: See answers above. In an electric circuit, the electric potential for a moving charge is gained in the battery and lost in a light bulb (or some resistor found in the external

circuit). So the electric potential of a charge is the same for any two points which are not separated by a battery or by a light bulb. (a through d)

Electric current is equal to the number of Coulombs of charge which move past a point on a circuit per unit of time. Electric current provides a measure of how fast charge moves between two points on a circuit. The electric current diminishes in

value as charge progresses to locations further and further from the + terminal of the battery. The electric current in a circuit will increase as the electric potential impressed across a circuit is increased.

Answer: A circuit which is complete in all respect, i.e., its all connections are intact is called a closed circuit. When the switch is on, the current flows in it and the bulb glows (Fig. 12.22a). On the other hand, a circuit is called open or not complete (Fig. 12.22b), when connections are

not intact, i.e., broken.
